Introduction

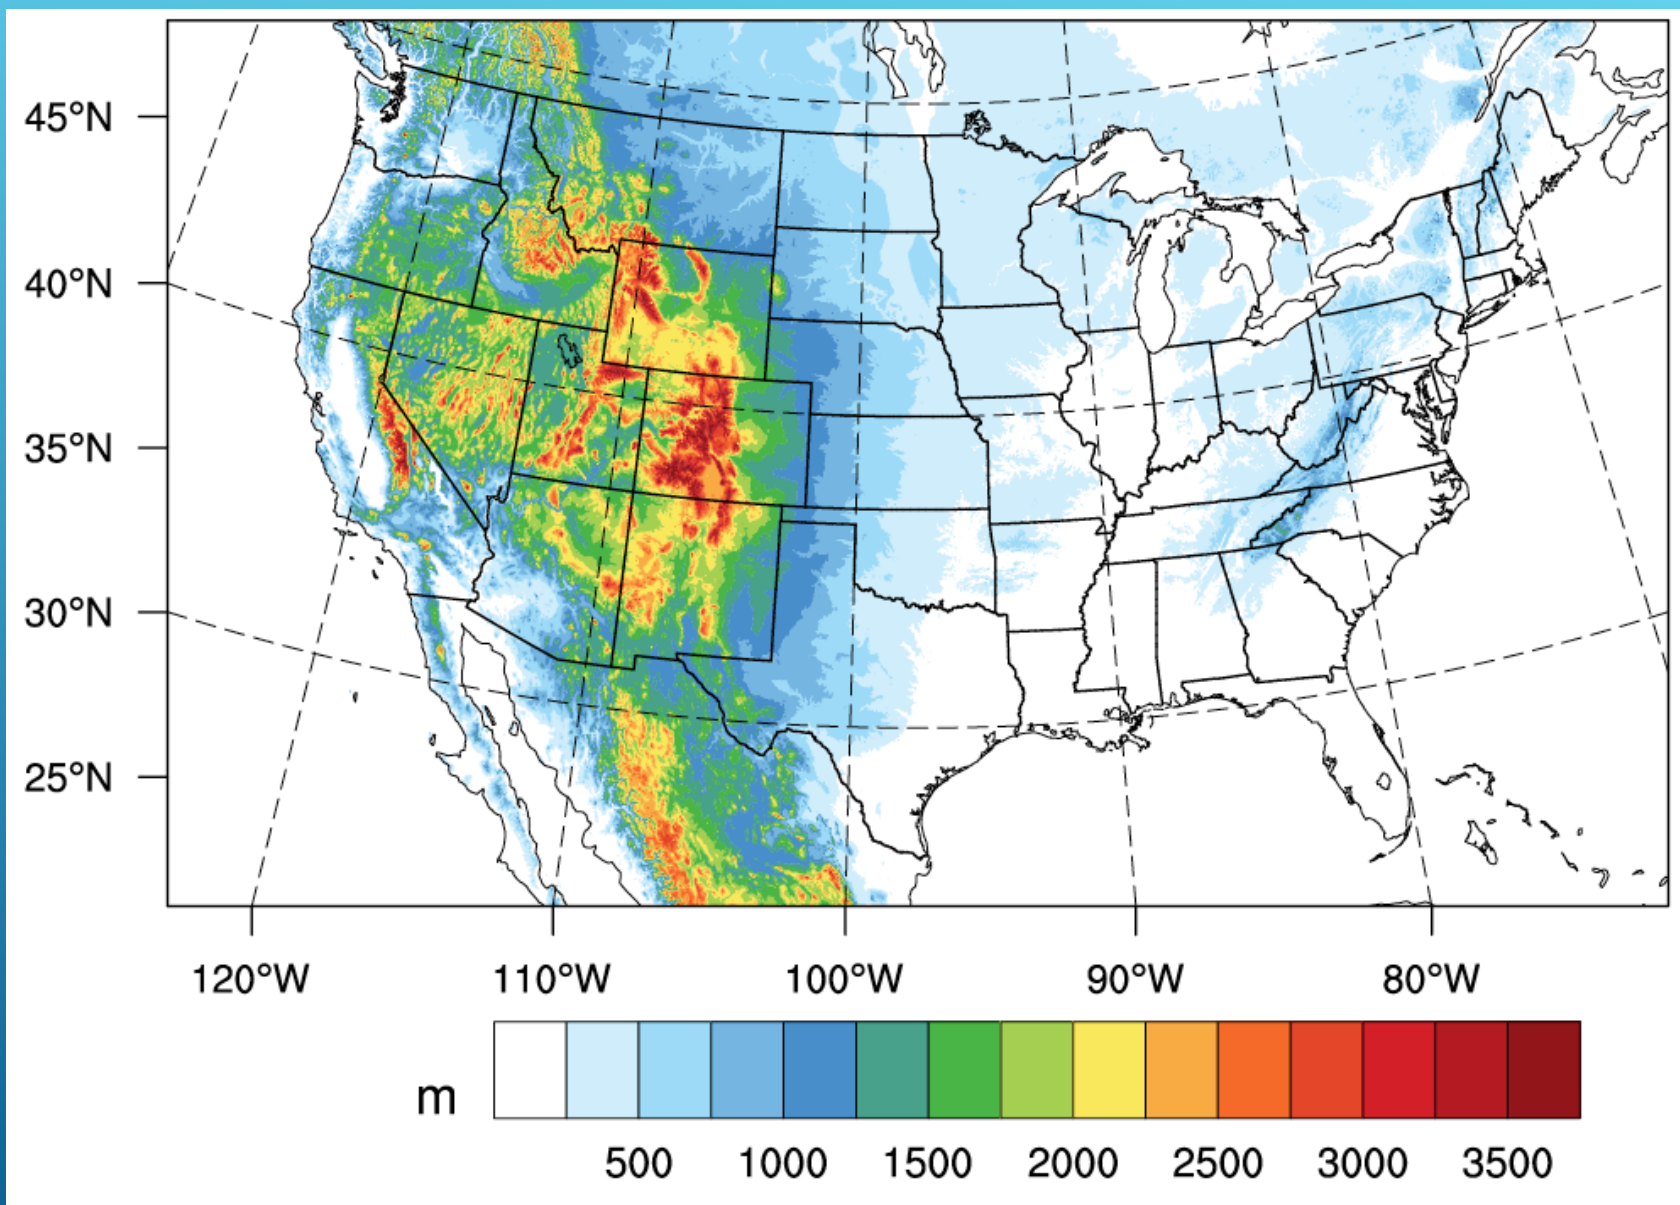

- High Resolution Rapid Refresh (HRRR) is a numerical weather prediction system running operationally at the National Center for Environmental Prediction (NCEP) and in real time at NOAA Earth System Research Laboratory/ Global Systems Division (NOAA/ESRL/GSD).
- The HRRR modeling system has been developed and tested at NOAA/ESRL/GSD. The HRRR modeling system is based on the Weather Research and Forecasting (WRF) model.
- Currently offline air quality models with relatively coarser resolution are mostly used for smoke forecast. A very few air quality models use the satellite Fire Radiative Power (FRP) data to predict fire emissions and plume rise.
- The goal of this project “**Towards the Inclusion of VIIRS Fire Products into the HRRR Real-Time Forecasts**” funded by the JPSS proving ground and risk reduction program is to include the **VIIRS products like active fire location and FRP data** into a coupled air quality model (**HRRR-Smoke**), in order to improve the numerical prediction of fire emissions and smoke dispersion in forecast models used at NOAA, also to study smoke impact on weather.
- The HRRR-Smoke model (modified version of the WRF-Chem online air quality model) configuration is based on the HRRR model with added smoke tracer emitted as fine particulate matter by biomass burning emissions (including simulation of plume rise by the model).

The Rapid Refresh and High-Resolution Rapid Refresh (<http://ruc.noaa.gov>)

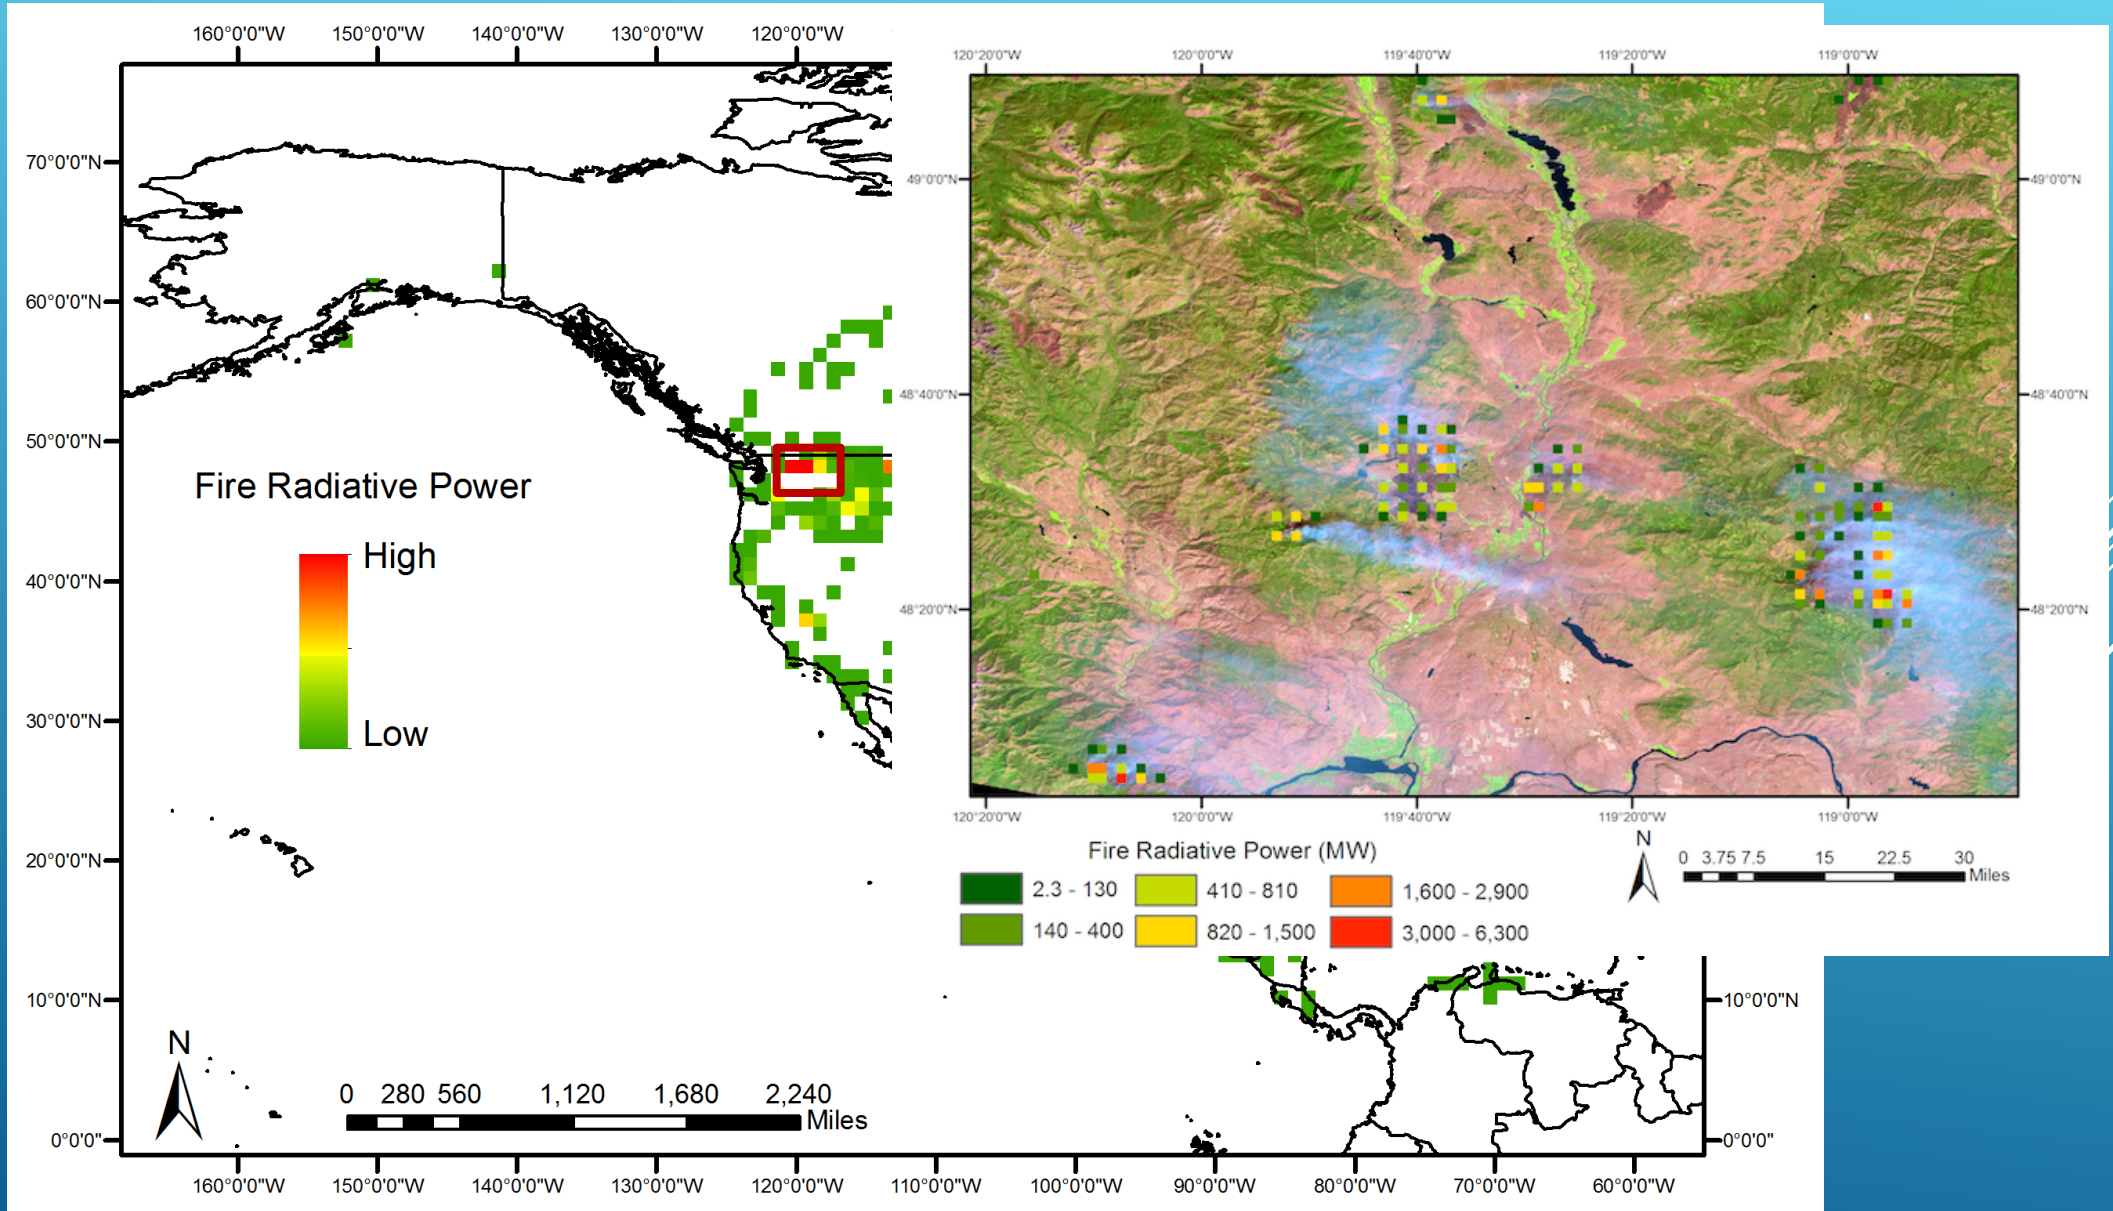

- The **Rapid Refresh (RAP)** is the continental-scale NOAA **hourly-updated** assimilation/modeling system operational at NCEP. RAP covers **North America** and is comprised primarily of a numerical forecast model and an analysis/assimilation system to initialize that model. RAP is complemented by the higher-resolution 3km **High-Resolution Rapid Refresh (HRRR)** model, which is also updated hourly and covering a smaller geographic domain.
- The **HRRR** is a NOAA real-time **3-km resolution, hourly updated, cloud-resolving, convection-allowing** atmospheric model, initialized by 3km grids with 3km radar assimilation. Radar data is assimilated in the HRRR every 15 min over a 1-h period adding further detail to that provided by the hourly data assimilation from the 13km radar-enhanced Rapid Refresh.
- The **experimental HRRR** is run by NOAA/ESRL/GSD as a real-time demonstration of advanced versions of the HRRR, ahead of the NCEP operational version. Experimental versions of the HRRR started to run in **2010** and from October 2014 onward, continuing to run more advanced versions than the NCEP operational version but with slightly lower reliability. Usually yearly upgrades are made at ESRL.
- HRRRv2 physics description in Benjamin et al. 2016, A North American Hourly Assimilation and Model Forecast Cycle: The Rapid Refresh. *Mon. Wea. Rev.* **44**, 1669-1694.

VISIBLE INFRARED IMAGING RADIOMETER SUITE (VIIRS) FRP DATA AUGUST 15-31, 2015

Mapping the VIIRS FRP data to the HRRR-Smoke CONUS grid

The clustering procedure performs a combination of all detected fires from VIIRS according to the model spatial resolution and grid configuration.

Averaged VIIRS FRP data mapped over 3x3km HRRR CONUS grid pixels for September 9, 2016

Smoldering and flaming emissions in HRRR-Smoke

To calculate plume rise we need to know heat flux.
 The traditional approach in the model to calculate plume rise:
 Use constant fire released heat flux numbers for a given land use class,
 e.g. Tropical Forest: min and max heat flux = 30, 80 kW/m²

New approach:

Heat flux ~ FRP/ burnt_area

FRP measured by satellites, in this case VIIRS

Burnt_area is determined by using fire size

smoldering term: $E_{\eta} = \rho_{air} \Delta z_{first\ phys.\ model\ layer}$

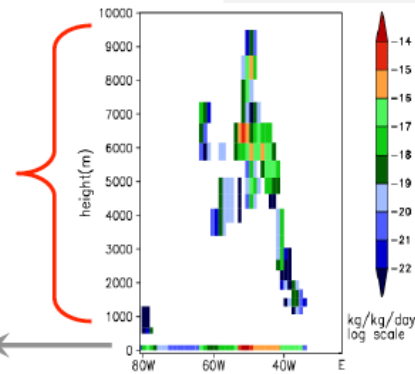

flaming term: $E_{\eta} = \frac{(1 - \lambda) F_{\eta}}{\rho_{air} \Delta z_{injection\ layer}}$

Example in the model:

flaming emission

smoldering emission

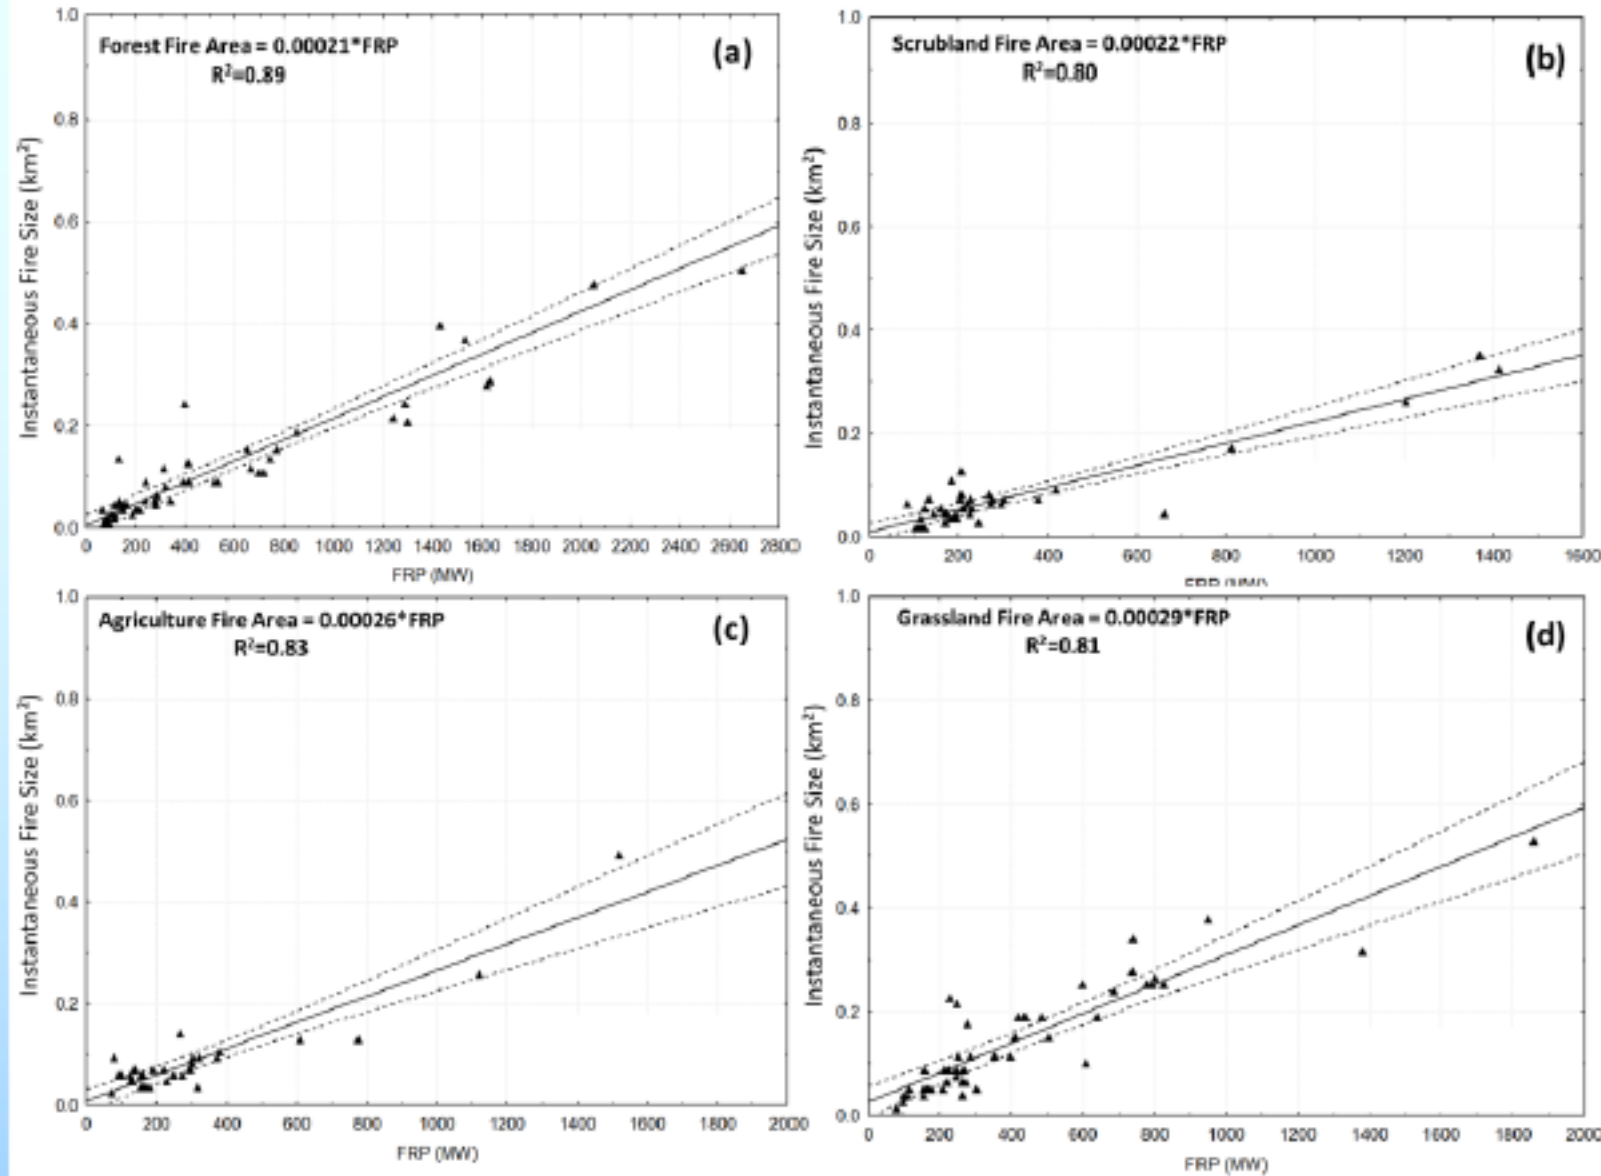

diurnal cycle of the burning for S. America:

$$E_{\eta}(t) = r(t)E_{\eta}$$

Workflow of the real-time HRRR-Smoke modeling system

- The **experimental HRRR-Smoke** started in June, 2016.
- The system is run 4 times a day at 00, 06, 12 and 18 UTC. It takes ~4 hours to complete entire cycle. Forecast plots are posted as simulations progress.
- Two NOAA HPC systems (Jet and Theia) are used.
- Multiple real-time datasets (meteorological observations, GFS model output, satellite...) are used.
- The forecast lead time is **36 hours**.

The “Fire Radiative Power” plots (rapidrefresh.noaa.gov/HRRRsmoke)

The FRP data are processed during HRRR-Smoke initialization by processing FRP for the model domain detected during previous 24 hours by VIIRS. Then the model simulates fire emissions and plume rise using the static FRP fields for 36 hours of smoke forecast. The following plot shows processed FRP values from VIIRS for the model grid cells (each size of 3x3 km) containing fires for 6Z September 14th, 2016 experimental smoke forecast.

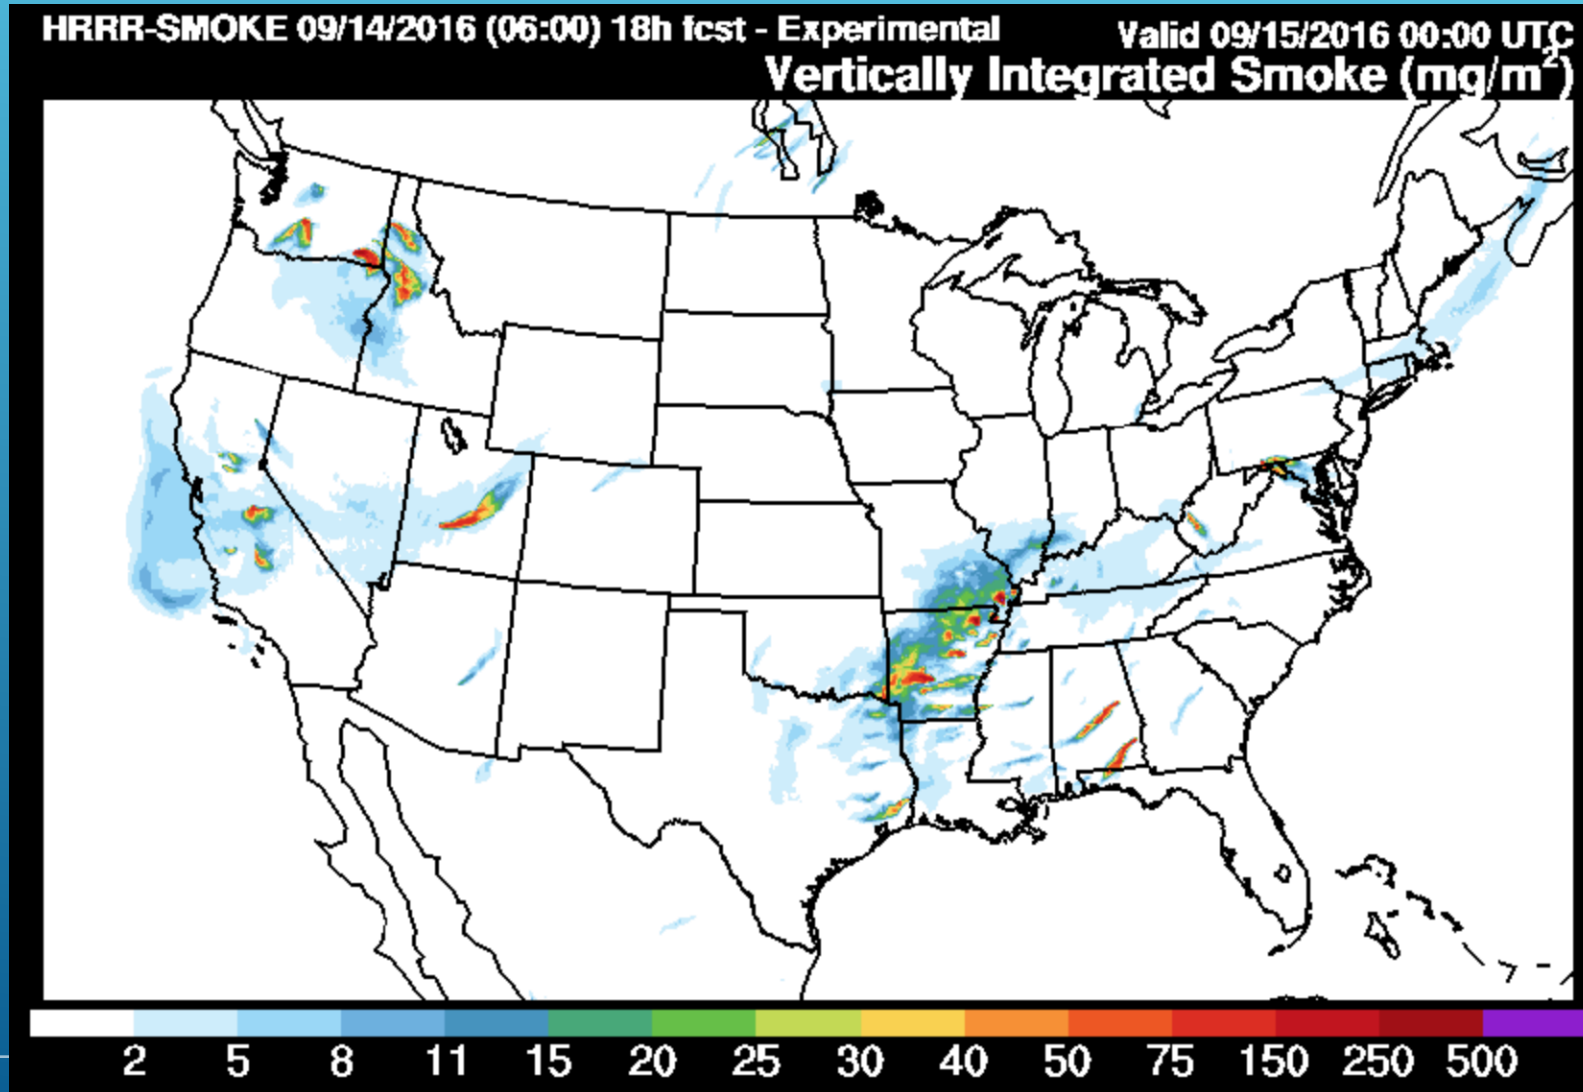

The “near surface fire smoke” plots (rapidrefresh.noaa.gov/HRRRsmoke)

This plot shows simulated fire emitted fine particulate matter (PM2.5 or fire smoke) concentrations at the first model level (~8m above ground). The following plot shows forecast of near-surface fire smoke for Sep 14th, 8pm EDT over the CONUS domain. This forecast is based on the model simulation of 18 hours from the model initialization time, which is 2am EDT, Sep. 14th.

The “vertically integrated fire smoke” plots (rapidrefresh.noaa.gov/HRRRsmoke)

This plot shows simulated total PM_{2.5} mass within vertical columns over each model grid cell (or fire smoke). These columns reach as high as ~25 km above ground. The purpose of showing such plots is to display the effect of fire smoke load which includes smoke in boundary layer as well as aloft, illustrating the integral effect of fire smoke throughout the atmosphere. The following plot shows a forecast of vertically integrated fire smoke for Sep 14th 8pm EDT.

Summary and future plans

- The HRRR-Smoke modeling system has been running in real-time at NOAA/ESRL/GSD providing users with 36 hourly smoke predictions in high spatial resolution.
- We have been getting valuable feedback from various users – IMETs, regional National Weather Services on the real-time HRRR-Smoke products.
- We plan working on better characterization of the diurnal cycle of fire emissions.
- Add another fire satellite detection data (MODIS)
- Study smoke impact on numerical weather prediction
- Synergy with other smoke forecast models: NAM-CMAQ, Blue Sky...
- Explore feasibility of HRRR-Smoke becoming an operational forecasting system at NCEP
